

# Identifying High Resource Consumption Supply Chain Points: A Case Study in Automobile Production

Douglas Thomas, Anand Kandaswamy, and Joshua Kneifel

**Abstract:** The Pareto principle posits that roughly 80 % of a problem is due to 20 % of the causes, allowing for the targeting of specific efficiency solutions. This paper examines whether the resources used in production are consistent with this principle and then seeks to develop a method to identify those supply chain entities that account for a disproportionately high level of resource consumption compared to other supply chain entities. A novel multi-factor approach is used where resources examined include time, cost, labor, environmental impact, and depreciable assets. The method utilizes data from the BEA 2007 Benchmark make and use tables, Annual Survey of Manufactures, Survey of Plant Capacity Utilization, Manufacturing Energy Consumption Survey, RS Means construction cost data, and an environmentally extended Input-Output database for Life Cycle Assessment (LCA). The approach facilitates the identification of economy-wide opportunities for efficiency improvement in manufacturing, a topic that has limited research devoted to it. Those production activities that consume high levels of resources provide a strong opportunity for efficiency improvement, affecting multiple stakeholders. This method is illustrated by examining automobile manufacturing as a case study. The results suggest that the cost distribution is consistent with the Pareto principle where 20 % of supply chain entities account for 89 %, 89 %, and 91 % of value added, labor hours, and environmental impacts from automobile manufacturing, respectively. Additionally, sixteen supply chain entities were above the 90<sup>th</sup> percentile in value added, environmental impact, and labor hours for automobile manufacturing, implying efficiency improvements could be obtained across multiple resources simultaneously. For those supply chain entities that would, traditionally, be considered a supplier (i.e., those that manufacture intermediate parts, components, and materials as opposed to those that provide services), the environmental impact, flow time, labor hours, and depreciable assets were above the 90<sup>th</sup> percentile for one supply chain entity and an additional two are above the 80<sup>th</sup> percentile.

## 1. Introduction

To achieve economy-wide efficiency improvements, researchers have suggested that “the supply chain must become the focus of policy management, in contrast to the traditional emphasis on single technologies/industries.”<sup>1</sup> System-level inefficiencies can result from companies working independently from one another, such as through the “bullwhip effect” where variations in demand are magnified through a supply chain.<sup>2,3</sup> Another issue lies in the location of supply chain entities. Manufacturers individually decide on the location of production, but individual decisions may not result in an efficient national supply chain arrangement. Firm level analyses of data can also be a source of inefficiencies, as this can hide economy-wide impacts. For example, a firm might conclude that their transportation cost represents a small portion of their total; however, it is reasonable to expect that they would not consider their suppliers’ transportation costs included in material purchases. The result is that the true cost of transportation through the manufacturing life-cycle may not be examined at the firm level.

One of the economic benefits of efficiency and productivity improvements in production is long term economic growth and increases in per capita income.<sup>4</sup> The US is among the highest per capita GDP

countries in the world<sup>5</sup> and to maintain this high level of income, the US must continue to advance efficiency and productivity in its economy. However, as factory level and individual supply chain level efficiency improvements are exhausted, it will become necessary to further examine production issues that span across establishments, industries, and supply chains. As a whole, the US has experienced a slowdown in productivity since 2004, resulting in GDP being \$2.7 trillion less than it might be otherwise.<sup>6</sup> With a multitude of products, processes, and activities, a holistic approach will require a systematic method to examine production across these factors. The standard categorization of labor and industry activity combined with Input-output analysis, which was originally developed by economist Wassily Leontief,<sup>7</sup> provides a foundation for such an approach. Input-output models are typically used to estimate the impact of a shift in demand for a good or service, but they also provide information on inter-industry activity, making such models an invaluable resource for industry-by-industry resource use within the US economy.

A frequently invoked axiom posits that roughly 80 % of a problem can be traced to 20 % of the cause(s), a phenomenon referred to as the Pareto principle.<sup>8</sup> This paper examines whether the costs and resources used in production are consistent with Pareto's principle, with a small fraction of the supply chain accounting for most of the resource consumption. It then seeks to advance the identification of those supply chain entities that account for a disproportionately high level of resource consumption. A method is developed and used to examine automobile manufacturing as a case study. Automobile manufacturing represents a large industry with many intermediate parts and components, making it a favorable case study for examining the supply chain. A multi-factor approach is used where five measures of resource consumption are examined: material flow time, cost measured in value added, labor cost, environmental impact, and gross depreciable assets. The statistical dispersion of value added, labor hours by industry, labor hours by occupation, and environmental impacts is measured using the Gini coefficient. The purpose of this approach is to facilitate the identification of economy-wide opportunities for efficiency improvement in manufacturing. Those production activities that consume high levels of resources provide a strong opportunity for efficiency improvement affecting multiple stakeholders. Public entities, trade organizations, and other change agents that seek to maximize efficiency improvement through innovative solutions must prioritize their efforts to get the largest reduction per expenditure dollar. It is important to note that there are a number of factors that are relevant to choosing the most economical investments to improve efficiency. The approach in this paper is a tool for examining one of those factors.

## 2. Methods

This paper uses input-output data and analysis to examine various aspects of the supply chain for manufacturing. Figure 1 illustrates the supply chain analysis being conducted. Industries are categories of establishments (i.e., physical locations of economic activity) based on the product being produced and the processes being used. Commodities (i.e., products and services) are exchanged between industries and are also delivered to the final consumer. For a particular finished commodity, in this case automobiles, a number of values are estimated: the amount of value added from each industry, the total cost of labor by

occupation, the environmental impact from each industry, the value of associated gross depreciable assets from each industry, and the time it takes for a material to move through an industry (note that this flow time measure is only applicable to industries that handle materials). Flow time and the gross value of depreciable assets relate to the use of capital such as machinery and buildings. These two measures are only available for supply chain entities that are within the manufacturing industry. Thus, industries such as transportation and mining will be examined using value added, labor hours, and environmental impact. Labor is analyzed as the sum of a particular labor category needed from all industries to produce a commodity, in this case automobiles (e.g., the sum of the red labor category from Industry A, B, and C to produce the finished commodity shown in Figure 1). The five measures together identify supply chain entities where multiple types of resources are being consumed at high levels. Below is a description of how the estimates are calculated. The methods in this paper build on those in Thomas and Kandaswamy (2016)<sup>9</sup>, Thomas and Kandaswamy (2016)<sup>10</sup>, and Thomas and Kneifel (2016).<sup>11</sup>

## 2.1. Industry Flow Time

Time is an important metric for measuring the use of capital because an increase in the time needed for production increases the necessary capital. This paper does not track the flow of physical goods *directly*, but rather tracks the flow of costs, which parallels the flow of physical goods.<sup>12</sup> This paper uses the term flow time, which might also be referred to as throughput time: the time that elapses between buying raw materials for the production process and selling the finished product.<sup>13</sup>

The calculation for flow time can be thought of as water flowing through a hose into a bucket. The cost of goods sold, *COGS*, is the total amount of water that runs into the bucket over a period of time. The inventory values are the amount of water in the hose at any given time. Since we know the total amount of water that flowed out of the hose (i.e., the amount in the bucket or *COGS*), we can estimate how many times the hose was filled and emptied over that period of time (inventory turns) by dividing the amount in the bucket by the volume of the hose. This method makes the assumption of first-in first-out (FIFO), where the oldest goods on hand are sold first.<sup>14</sup> The proposed method for estimating the sum of the flow time for materials and supplies inventories, work-in-process inventories, and finished goods inventories for a particular NAICS code is:

Equation 1

$$FT_{IND,Total} = \sum_{i=1}^N IRR_{IND} \times \frac{(INV_{IND,i,BOY} + INV_{IND,i,Eoy})/2}{(INV_{IND,Total,BOY} + INV_{IND,Total,Eoy})/2} \times \frac{365}{TRN_{IND,Total}}$$

<sup>14</sup> Meigs and Meigs, 409.

Where

$FT_{IND,Total}$  = Total estimated flow time for industry  $IND$

$i$  = Inventory item where  $i$  is materials and supplies (MS), work-in-process (WIP), or finished goods (FG) inventories.

$INV_{IND,Total,BOY}$  = Total inventory (i.e., materials and supplies, work-in-process, and finished goods inventories) for industry  $IND$  at the beginning of the year

$INV_{IND,Total,EOY}$  = Total inventory (i.e., materials and supplies, work-in-process, and finished goods inventories) for industry  $IND$  at the end of the year

$TRN_{IND,Total}$  = Inventory turns for industry  $IND$  (defined below)

$IRR_{IND}$  = Industry reiteration rate for industry  $IND$  (defined below)

The days that a dollar spends in each of the inventory categories is being calculated by taking the total number of days in a year and dividing it by the number of inventory turns  $TRN$ , which is the number of times inventory is sold or used in a time period such as a year (see below). This is then multiplied by average inventory of type  $N$  divided by the total inventory. The product in the equation is adjusted by an industry reiteration rate  $IRR$ , which is an estimate of the number of times a material is processed in one industry (see below). Finally, the summation of all types of inventory is calculated for industry  $IND$ . Work-in-process inventories can be broken into two categories: 1) work-in-process and 2) work-in-process downtime when the factory is closed. The analysis of time flow will focus on work-in-process, as this is the time spent on production. This calculation is discussed below.

*Inventory Turns*: Inventory turns,  $TRN_{Total}$ , is the number of times inventory is sold or used in a time period such as a year.<sup>15, 16, 17</sup> It is calculated as the cost of goods sold (COGS), which is the cost of the inventory that businesses sell to customers,<sup>18</sup> divided by the average inventory:

Equation 2

$$TRN_{Total} = \frac{COGS}{\left(\frac{INV_{Total,BOY} + INV_{Total,EOY}}{2}\right)}$$

Where

$COGS = AP + FB + MAT + DEP + RP + OTH + (INV_{Total,BOY} - INV_{Total,EOY})$

$AP$  = Annual payroll

$FB$  = Fringe benefits

<sup>15</sup> Horngren, Harrison, Smith, and Bamber, 186.

<sup>16</sup> Stickney, Clyde P. and Paul R. Brown. Financial Reporting and Statement Analysis. Mason, OH: Southwestern, 1999. 136-137.

<sup>17</sup> Hopp and Spearman. 230.

<sup>18</sup> Horngren, Harrison, Smith, and Bamber, 168.

$MAT$  = Total cost of materials

$DEP$  = Depreciation

$RP$  = Rental payments

$OTH$  = Total other expenses

Inventory turns is usually stated in yearly terms and is used to study a number of fields, such as distributive trade, particularly with respect to wholesaling.<sup>19</sup> The data for calculating  $COGS$  is from the Annual Survey of Manufactures. In the previous two equations, inventories are calculated using the average of the beginning of year inventories and end of year inventories, which is standard practice.<sup>20</sup>

*Industry Reiteration Rate:* The reiteration rate is an estimate of the number of times a material is processed in one industry. A material may go through more than one establishment in an industry. For example, a chemical plant could produce chemical A while another plant produces chemical B from chemical A. Both establishments are in the same industry because they both make chemicals, which would mean that the materials were in inventory approximately twice as long as would be calculated using only the inventory data from the Annual Survey of Manufactures (ASM). One can calculate the number of establishments a material goes through before it is diminished below a certain threshold using a logarithmic function with base  $P$ , which is the industry reiteration rate:

Equation 3

$$IRR = \log_p T$$

Where

$IRR$  = Industry reiteration rate

$P$  = Proportion of materials, parts, containers, packaging, and resales that are purchased from an establishment in the same industry (defined below).

$T$  = The selected threshold, which is between 0 and 1. The threshold represents the level of  $P$  at which it is believed materials would only go through one establishment in that industry; therefore, for values of  $P$  that are less than  $T$  the industry reiteration rate is 1. A threshold can be selected by examining  $P$  values from industries where a product only goes through one establishment in that industry. The threshold would then either be equal to one of those  $P$  values or based on them (e.g., average or maximum value). For those industries that are below the threshold, the reiteration rate is simply 1. The result is that the  $IRR$  is greater than or equal to one.

Two datasets are used to estimate  $P$ : the BEA Benchmark Input-Output Use data and the Annual Survey of Manufactures. The Benchmark Use table provides inter-industry purchases, including the purchases an industry makes from itself. The Annual Survey of Manufactures provides the total cost of materials, parts, containers, and packaging used as well as the cost of resales, which are items purchased and resold without being altered. The inter-industry purchases are divided by the sum of the cost of materials, parts, containers, and packaging used and the cost of resales.<sup>21</sup> This provides  $P$ , a proportion of material purchases from the same industry:

---

<sup>19</sup> Hopp and Spearman. 230.

<sup>20</sup> Horngren, Harrison, and Bamber. 725, 186.

<sup>21</sup> Resales include items bought and sold in the same condition.

Equation 4

$$P = \frac{\text{Purchases an Industry Makes from Itself}}{\text{Materials, Parts, Containers, and Packaging} + \text{Resales}}$$

This is an average proportion of materials purchased from another establishment within the same industry; thus, if  $P$  equals 0.3 for industry X, then, on average, an establishment in industry X purchases 30 % of its materials from other establishments in that industry.

The industry reiteration rate makes the basic assumption that establishments in an industry have similar  $P$  values because they compete against each other in producing similar products. As a material moves from one establishment to another, a proportion  $P$  of the material moves on to an establishment in the same industry. A proportion of that proportion then moves on to another establishment within the same industry. The log function estimates how many of these proportions a material goes through before it is diminished below the selected threshold by estimating to what power  $P$  must be raised to equal  $T$ . For example, let's say that industry X has a proportion  $P$  of 0.50 and one selects a threshold of 0.125. The industry reiteration rate would be:

$$IRR = \log_{0.5} 0.125 = 3$$

This suggests that, given this threshold, a material is likely to go through around three establishments in industry X, on average.

It must be noted that this is a proxy measure. In order to know the average number of establishments a material travels through, it would be necessary to map the interactions of the hundreds, thousands, and even tens of thousands of establishments in each industry. Such an effort would be technically infeasible; therefore, we must rely on a proxy. Although the industry reiteration rate is not a precise measurement, it creates a multiplier that increases as an industry purchases more goods from itself relative to its purchases from other industries. It also provides a rate that can be compared between industries.

For the analysis, a threshold of 0.03 was selected. Industries that would be expected to go through only 1 establishment tended to have a  $P$  value of 0.03 or less. For example, printing is likely to go through only one establishment and had a  $P$  value of 0.028. Another example with a value of 0.002 is automobile manufacturing (i.e., assembly), which is an industry that is separate from auto parts production and, therefore, would likely only go through one establishment. The selected threshold should be appropriate for all industries, as it is applied to all the manufacturing industries in the supply chain. As the threshold is lowered the reiteration rate increases; therefore, a higher threshold moves toward assuming that a material moves through fewer establishments while a lower threshold moves toward assuming it moves through more establishments.

*Work-in-Process Downtime:* Flow time for work-in-process inventories ( $FT_{WIP}$ ) consists of two components: the time that a good is in work-in-process while the factory is open and the time that a good is in work-in-process while the factory is closed. Separating the two out is useful for understanding where the flow time occurs. The time when the factory is closed can be estimated by multiplying the total flow time for work in process by the ratio of total hours that the plant is open:

Equation 5

$$FT_{WIPD} = \left(1 - \frac{Hr_{Plnt}}{168}\right) \times FT_{WIP}$$

Where:

$FT_{WIPD}$  = Flow time for work-in-process downtime when the factory is closed

$Hr_{Plnt}$  = Average plant hours per week in operation from the quarterly Survey of Plant Capacity Utilization

$FT_{WIP}$  = Flow time for work-in-process

Breaking the flow time for work-in-process into time when the factory is open and closed aids in understanding the activities that are occurring during flow time.

The calculations for tracking flow time,  $FT$ , can be made for any individual NAICS code category. Materials flow from establishments in one NAICS code to establishments in another NAICS code. These movements can be traced using Input-Output data from the BEA. The Use table from the BEA Benchmark Input-Output tables provides the items each industry purchases from other industries, which was used to create a supply chain map. This data, however, includes not only the materials, but also the energy, machinery, services, and other items that are not part of the final product. To track the flow time and inventory time from NAICS code to NAICS code, it is necessary to identify only those activities that process materials that are physically part of the final product. To identify these activities, the data from the Use table that applies to manufacturing was extracted by examining the NAICS code descriptions and activities.

## 2.2. Environmental Impact

The measure of environmental impact is calculated using input-output analysis combined with TRACI 2 impact categories and the Analytical Hierarchy Process to weight the categories. A description of the calculations is below.

*Input-Output Analysis:* The Make-Use tables are used for Input-Output analysis.<sup>22</sup> The model operates under constant returns to scale and thus ignores potential economies of scale.<sup>23</sup> The model also assumes that a sector uses inputs in fixed proportions. These issues are, typically, relevant to analyses that examine the impact of a change in demand.<sup>24</sup> This paper is not seeking to predict the impact of a change in demand, but rather seeks to track the total resources used for the production of particular goods; therefore, ignoring economies of scale and assuming sectors use inputs in fixed proportions has minimal impact on this analysis. This paper also uses an industry-by-commodity Input-Output format as outlined in Horowitz and Planting (2006), which accounts for the fact that an industry may produce more than one commodity or product, such as secondary products and by-products.<sup>25, 26, 27</sup>

<sup>25</sup> Ibid.

<sup>26</sup> Miller. 184.

<sup>27</sup> European Commission. Eurostat Manual of Supply, Use, and Input-Output Tables. 2008 Edition. 2008. Accessed September 2016. <http://ec.europa.eu/eurostat/documents/3859598/5902113/KS-RA-07-013-EN.PDF/b0b3d71e-3930-4442-94be-70b36cea9b39?version=1.0>.

An input-output analysis develops a total requirements matrix that when multiplied by the vector of final demands equals the output needed for production. The total requirements matrix is developed using the methods outlined in Horowitz and Planting (2006):

Equation 6

$$X = W(I - BW)^{-1} * Y$$

Where:

$X$  = Vector of output required to produce final demand

$Y$  = Vector of final demand

$W = (I - \hat{p})D$

$B = U\hat{g}^{-1}$

$I$  = Identity matrix

$D = V\hat{q}^{-1}$

$p$  = A column vector in which each entry shows the ratio of the value of scrap produced in each industry to the industry's total output.

$U$  = Intermediate portion of the use matrix in which the column shows for a given industry the amount of each commodity it uses—including noncomparable imports, scrap, and used and secondhand goods. This is a commodity-by-industry matrix.

$V$  = Make matrix, in which the column shows for a given commodity the amount produced in each industry. This is an industry-by-commodity matrix.  $V$  has columns showing only zero entries for noncomparable imports and for scrap.

$g$  = A column vector in which each entry shows the total amount of each industry's output, including its production of scrap. It is an industry-by-one vector.

$q$  = A column vector in which each entry shows the total amount of the output of a commodity. It is a commodity-by-one vector.

$\hat{\phantom{x}}$  = A symbol that when placed over a vector indicates a square matrix in which the elements of the vector appear on the main diagonal and zeros elsewhere.

In Equation 6, a total requirements matrix  $W(I - BW)^{-1}$  is multiplied by a vector of final demand for commodities  $Y$  to estimate the total output  $X$ . All variables in Equation 6 have known values in the input output data. The output  $X$  required to produce an alternate level of final demand can be calculated by altering the final demand vector from the actual final demand  $Y$  in the input output data to  $Y'$ . For this analysis,  $Y'$  has the actual final demand for assembly-centric commodities and zero for other commodities. This alteration reveals the output needed to produce only assembly-centric commodities.

*Environmental Impact Categories:* The TRACI 2 impact categories are each an aggregation of multiple emissions converted to a common physical unit. For example, the global warming impact category includes impacts of many pollutants, such as carbon dioxide (CO<sub>2</sub>), methane (CH<sub>4</sub>), nitrous oxide (NO<sub>x</sub>), and fluorinated gases, which are converted to their carbon dioxide equivalent (CO<sub>2e</sub>) impact and aggregated to estimate the total impact for that impact category. The environmental impacts are measured in terms of the common physical unit per dollar of output. The impact can be calculated by multiplying the output in the Input-Output analysis by the impact categories.

*Impact Category Weights:* Having 12 environmental impact categories makes it difficult to rank industry environmental activity; therefore, the 12 impact categories have been combined into a single environmental metric using the Analytical Hierarchy Process (AHP). AHP is a mathematical method for developing weights using normalized eigenvalues. It involves making pairwise comparisons of competing items based on a multilevel hierarchy developed by the user. The weights used in this paper were developed for the BEES software and can be seen in Table 1.<sup>28</sup> This paper uses 12 of the 13 impact categories for which weights were developed. Indoor Air Quality (IAQ) is excluded because it is more applicable to the design of buildings and ventilation systems rather than to manufacturing activities. The weight of IAQ is proportionally allocated to the other 12 impact categories. The final metric for each industry or industry/commodity combination is the proportion of the total impact from assembly-centric products. The percent of environmental impacts, based on the weights, are calculated using the following equation:

Equation 7

$$\begin{aligned}
 Env_{z,Y'} = & \frac{x_{z,Y'} * GWP_z}{\sum_{i=1}^n x_{i,Y'} * GWP_i} * 0.30 + \frac{x_{z,Y'} * Acid_z}{\sum_{i=1}^n x_{i,Y'} * Acid_i} * 0.03 + \frac{x_{z,Y'} * HHA_z}{\sum_{i=1}^n x_{i,Y'} * HHA_i} * 0.09 \\
 & + \frac{x_{z,Y'} * Eut_z}{\sum_{i=1}^n x_{i,Y'} * Eut_i} * 0.06 + \frac{x_{z,Y'} * OD_z}{\sum_{i=1}^n x_{i,Y'} * OD_i} * 0.02 + \frac{x_{z,Y'} * Sm_z}{\sum_{i=1}^n x_{i,Y'} * Sm_i} * 0.04 \\
 & + \frac{x_{z,Y'} * Eco_z}{\sum_{i=1}^n x_{i,Y'} * Eco_i} * 0.07 + \frac{x_{z,Y'} * HHC_z}{\sum_{i=1}^n x_{i,Y'} * HHC_i} * 0.08 + \frac{x_{z,Y'} * HHNC_z}{\sum_{i=1}^n x_{i,Y'} * HHNC_i} * 0.05 \\
 & + \frac{x_{z,Y'} * PE_z}{\sum_{i=1}^n x_{i,Y'} * PE_i} * 0.10 + \frac{x_{z,Y'} * LU_z}{\sum_{i=1}^n x_{i,Y'} * LU_i} * 0.06 + \frac{x_{z,Y'} * WC_z}{\sum_{i=1}^n x_{i,Y'} * WC_i} * 0.08
 \end{aligned}$$

Where

$Env_{z,Y'}$  = Environmental impact from industry  $z$  for final demand  $Y'$

$GWP_z$  = Global warming potential per dollar of output for industry  $z$

<sup>28</sup> Lippiatt, Barbara, Anne Landfield Greig, and Priya Lavappa. Building for Environmental and Economic Sustainability. National Institute of Standards and Technology. 2010. Accessed September 2016. <http://www.nist.gov/el/economics/BEESSoftware.cfm>.

$Acid_z$  = Acidification per dollar of output for industry  $z$

$HHA_z$  = Human health –criteria air pollutants – per dollar of output for industry  $z$

$Eut_z$  = Eutrophication per dollar of output for industry  $z$

$OD_z$  = Ozone depletion per dollar of output for industry  $z$

$Sm_z$  = Smog per dollar of output for industry  $z$

$Eco_z$  = Ecotoxicity per dollar of output for industry  $z$

$HHC_z$  = Human health – carcinogens – per dollar of output for industry  $z$

$HHNC_z$  = Human health – non-carcinogen – per dollar of output for industry  $z$

$PE_z$  = Primary energy consumption per dollar of output for industry  $z$

$LU_z$  = Land use per dollar of output for industry  $z$

$WC_z$  = Water consumption per dollar of output for industry  $z$

$x_{z,Y'}$  = Output for industry  $z$  with final demand  $Y'$

*Energy*: One challenge with examining the impacts of manufacturing by industry is that energy impacts become disaggregated into multiple industries such as mining, transportation, and electricity generation. However, an efficiency improvement in energy use within a factory has immediate implications for the impact associated with energy and its supply chain; therefore, energy should be treated as a single unit rather than disaggregated entities. To address this issue, an estimate of the aggregated impacts of energy is examined by altering the final demand vector  $Y$  in Equation 6 to the final demand vector  $Y''$  where the final demand for “*electric power generation, transmission, and distribution*” is equal to 1 and demand for all other commodities in the final demand vector  $Y''$  is set to zero. This allows us to calculate the environmental impacts from each industry to produce a unit of impact from assembly-centric manufacturing:

Equation 8

$$\begin{aligned}
 Env_{z,Y''} = & \frac{x_{z,Y''} * GWP_z}{\sum_{i=1}^n x_{i,Y'} * GWP_i} * 0.30 + \frac{x_{z,Y''} * Acid_z}{\sum_{i=1}^n x_{i,Y'} * Acid_i} * 0.03 + \frac{x_{z,Y''} * HHA_z}{\sum_{i=1}^n x_{i,Y'} * HHA_i} * 0.09 \\
 & + \frac{x_{z,Y''} * Eut_z}{\sum_{i=1}^n x_{i,Y'} * Eut_i} * 0.06 + \frac{x_{z,Y''} * OD_z}{\sum_{i=1}^n x_{i,Y'} * OD_i} * 0.02 + \frac{x_{z,Y''} * Sm_z}{\sum_{i=1}^n x_{i,Y'} * Sm_i} * 0.04 \\
 & + \frac{x_{z,Y''} * Eco_z}{\sum_{i=1}^n x_{i,Y'} * Eco_i} * 0.07 + \frac{x_{z,Y''} * HHC_z}{\sum_{i=1}^n x_{i,Y'} * HHC_i} * 0.08 + \frac{x_{z,Y''} * HHNC_z}{\sum_{i=1}^n x_{i,Y'} * HHNC_i} * 0.05 \\
 & + \frac{x_{z,Y''} * PE_z}{\sum_{i=1}^n x_{i,Y'} * PE_i} * 0.10 + \frac{x_{z,Y''} * LU_z}{\sum_{i=1}^n x_{i,Y'} * LU_i} * 0.06 + \frac{x_{z,Y''} * WC_z}{\sum_{i=1}^n x_{i,Y'} * WC_i} * 0.08
 \end{aligned}$$

From Equation 8, the indirect impact of electricity (i.e., the impact from other industries such as mining and transportation associated with electricity production) per percentage point of direct impact can be estimated:

Equation 9

$$IIPP_E = \frac{[\sum_{i=1}^n Env_{z,Y''}] - Env_{E,Y''} - Env_{Nat,Y''}}{Env_{E,Y''}}$$

Where

$IIPP_E$  = Indirect Impact per percentage point of direct impact from “*electric power generation, transmission, and distribution*”

$Env_{E,Y''}$  = Environmental impact from the “*electric power generation, transmission, and distribution*” for final demand  $Y''$

$Env_{Nat,Y''}$  = Environmental impact from the “*natural gas distribution*” for final demand  $Y''$

A similar calculation can be made for natural gas where final demand for  $Y''$  is set to 1 for “*natural gas distribution*” and zero for all other commodities:

Equation 10

$$IIPP_{Nat} = \frac{[\sum_{i=1}^n Env_{z,Y''}] - Env_{E,Y''} - Env_{Nat,Y''}}{Env_{Nat,Y''}}$$

Where

$IIPP_{Nat}$  = Indirect Impact per percentage point of direct impact from natural gas

Equation 9 and Equation 10 calculate and parse out the indirect impacts of the energy consumed from the production of assembly-centric manufacturing while incorporating the weights previously discussed.

An additional issue with energy is that it is associated with completely different types of processes and purposes. Some energy is used for heating and cooling of buildings while other energy is used for operating machinery. Grouping these together masks the source of energy consumption. The BEA Input-Output data provides estimates of energy use; however, it does not provide the detail in how the energy is used, which would allow for a more targeted approach to addressing energy efficiency improvements. In order to better understand energy use, the Manufacturing Energy Consumption Survey (MECS) was used to separate the BEA energy data into use categories to show both the quantity of energy consumption as well as the purpose for which the consumption occurs. The energy use categories provided include: *indirect uses-boiler fuel, process heating, process cooling and refrigeration, machine drive, electro-chemical processes, other process use, facility HVAC, facility lighting, facility support, onsite transportation, other non-process use, and end use not reported*. Electric power generation, transmission, and distribution from the BEA data is broken into these categories by portioning out coal mining, electricity generation, and natural gas distribution by proportions calculated from the Energy Information Administration (EIA). The MECS data and BEA data both have varying levels of NAICS code aggregation. The MECS data can be aggregated up when it is more detailed than the BEA data. When the BEA data is more detailed it is assumed that the proportions remain the same for the detailed NAICS codes. This issue illustrates the need for advanced coordination between data collection entities.

### 2.3. Value Added

The total requirements matrix  $W(I - BW)^{-1}$  from Equation 6, which shows the total output required to meet a given level of final demand, is multiplied by final demand in the input-output data to estimate the

total output. The output required to produce a particular level of final demand can be calculated by altering final demand to  $Y'$ . For this analysis,  $Y'$  equals final demand for those NAICS codes representing assembly-centric products and zero for those that do not, making this an examination of assembly-centric products and their supply chains.

Value added is calculated by assuming the proportion of output needed to produce a commodity is the same proportion of value added, which is consistent with methods proposed by Miller (2009). The proportions calculated using the input-output analysis are then multiplied by the value added and scaled to 2014 dollars using the estimate of gross output for that year:

Equation 11

$$VA_{z,Y',2014} = \frac{x_{z,Y',2007}}{x_{z,2007}} * VA_{z,2007} * \left( \frac{x_{z,2014}}{x_{z,2007}} \right)$$

Where

$VA_{z,Y',2014}$  = Value added from industry  $z$  with final demand  $Y'$  in 2014

$x_{z,2007}$  = Total output for industry  $z$  in 2007

$x_{z,2014}$  = Total output for industry  $z$  in 2014

$x_{z,Y',2007}$  = Output for industry  $z$  with final demand  $Y'$  in 2007

$VA_{z,2007}$  = Total value added from industry  $z$  in 2007

Imports are calculated in a similar fashion, where the proportion of total output used from a particular industry is the same for imports.

*Energy Analysis:* Similar to the environmental analysis, value added was broken into energy use categories including: *indirect uses-boiler fuel, process heating, process cooling and refrigeration, machine drive, electro-chemical processes, other process use, facility HVAC, facility lighting, facility support, onsite transportation, other non-process use, and end use not reported.*

## 2.4. Labor

In order to examine labor activity, Bureau of Labor Statistics employment data from the Occupational Employment Statistics is matched with the BEA IO NAICS categories. For this analysis, the Bureau of Labor Statistics employment data has been mapped to the detail level found in the 2007 Benchmark Input-Output data. In instances where the NAICS codes for the occupation data did not match that of the input-output data, the values were estimated. When the BEA data had a NAICS code at a lower level of detail than the occupation data, the occupation data was aggregated up to the BEA level of detail. If the occupation data was at a lower level of detail, then the BEA levels were estimated by assuming the proportion of the cost of compensation in the BEA was the same as that for employment. This provides an estimate of occupational employment by industry at the NAICS level of detail. To estimate the hours of labor, these estimates are multiplied by the average hours per week for each occupation and by the total weeks per year. These hours are then multiplied by wages per hour and adjusted to match the BEA estimates of compensation assuming the BEA proportions of labor are the same as that calculated using BLS data. When examining a specific product commodity such as automotive manufacturing, the input-

output calculations are used to estimate the output from each industry required to produce the given product. The proportion of the total output needed from each industry is multiplied by the occupational employment for each industry to estimate the amount of labor, which is consistent with methods proposed in Miller (2009). The result is a matrix of the amount of labor needed, categorized by NAICS by occupation, to produce the relevant commodity.

Equation 12

$$C_{z,s,Y'} = \frac{x_{z,Y'}}{x_z} * C_{z,s} * \left( \frac{E_{z,s} * LH_s * W_{z,s}}{\sum_{i=1}^n E_{z,i} * LH_s * W_{z,i}} \right) * \left( \frac{x_{z,2014}}{x_{z,2007}} \right)$$

Where

$C_{z,s,Y'}$  = Compensation for occupation s in industry z with final demand  $Y'$

$C_{z,s}$  = Total compensation for occupation s in industry z

$x_z$  = Total output for industry z

$x_{z,Y'}$  = Output for industry z with final demand  $Y'$

$E_{z,s}$  = Employment for industry z and occupation s

$LH_s$  = Labor hours per employee for occupation s

$W_{z,s}$  = Hourly wages per employee for industry z and occupation s

## 2.5. Gross Value of Depreciable Assets

Depreciable assets are measured in a similar fashion to labor. The proportion of output estimated from the input-output calculations is multiplied by the total depreciable assets for that industry, resulting in an estimate of depreciable assets utilized for the production of the commodity being examined. An estimate for buildings and machinery/equipment is made by utilizing RS Means data. The total square footage of manufacturing space from the Manufacturing Energy Consumption survey is multiplied by the average construction cost per square foot from RS Means. This is assumed to be the buildings share of depreciable assets with the remaining amount assumed to be machinery/equipment:

Equation 13

$$DB_{z,Y'} = \frac{x_{z,Y',2007}}{x_{z,T,2007}} * (SF_z * RM)$$

Equation 14

$$DM_{z,Y'} = \left[ \frac{x_{z,Y',2007}}{x_{z,T,2007}} * DA_z \right] - DB_{z,Y'}$$

Where

$DB_{z,Y',MB}$  = Depreciable building assets from industry z associated with final demand  $Y'$  in 2014

$DM_{z,Y'}$  = Depreciable machinery assets from industry  $z$  associated with final demand  $Y'$  in 2014

$x_{z,T,2007}$  = Total output for industry  $z$  in 2007

$x_{z,Y',2007}$  = Output for industry  $z$  with final demand  $Y'$  in 2007

$SF_z$  = Estimated square feet of manufacturing floor space for industry  $z$

$RM$  = RS Means estimated construction cost per square foot of manufacturing floor space

$DA_z$  = Gross value of depreciable assets (end of year) from the annual survey of manufactures

A similar calculation is made for the purchase of new and used capital assets, where the proportion of output estimated from the input-output calculations is multiplied by the value of new and used capital assets purchased.

Equation 15

$$CE_{z,Y',MB} = \frac{x_{z,Y',2007}}{x_{z,T,2007}} * CE_{MB}$$

Where

$CE_{z,Y',MB}$  = Capital expenditures by industry  $z$  with final demand  $Y'$  on MB, where MB is either machinery or buildings

$x_{z,T,2007}$  = Total output for industry  $z$  in 2007

$x_{z,Y',2007}$  = Output for industry  $z$  with final demand  $Y'$  in 2007

$CE_{z,MB}$  = Total capital expenditures by industry  $z$  on MB, where MB is either machinery or buildings

### 3. Data

There are a number of datasets needed to examine costs, environmental impacts, time flow, and capital. These datasets include the Annual Survey of Manufactures from the US Census Bureau, the Economic Census from the US Census Bureau, the Bureau of Economic Analysis (BEA) Benchmark Input-Output data, environmentally extended input-output data, Occupational Employment Statistics from the Bureau of Labor Statistics, Energy Consumption Survey from the Energy Information Administration, and RS Means cost data. These datasets are described below.

*Input-Output Data:* Every five years the BEA computes benchmark input-output tables, which tends to have over 350 industries.<sup>29</sup> The data is provided in the form of make and use tables, with their corresponding matrices replacing the Leontief method.<sup>30</sup> In the US, industries are categorized by NAICS codes. There are two types of make and use tables: “standard” and “supplementary.” Standard tables closely follow NAICS and are consistent with other economic accounts and industry statistics, which classify data based on establishment. Note that in this context an “establishment” is a single physical

---

<sup>29</sup> Bureau of Economic Analysis. Input-Output Accounts Data. November 2014. Accessed September 2016. [http://www.bea.gov/industry/io\\_annual.htm](http://www.bea.gov/industry/io_annual.htm).

<sup>30</sup> A System of National Accounts, Studies in Methods, Series F/No. 2/Rev. 3, New York, United Nations, 1968.

location where business is conducted. This should not be confused with an “enterprise” such as a company, corporation, or institution. Establishments are classified into industries based on the primary activity within the NAICS code definitions; however, establishments often have multiple activities. An establishment is classified based on its primary activity. Data for an industry reflects all the products made by the establishments within that industry; therefore, secondary products are included. Supplementary make-use tables reassign secondary products to the industry in which they are primary products. The data in this report utilizes the standard make-use tables.

*Manufacturing Data:* The Annual Survey of Manufactures (ASM) is conducted every year except for when the Economic Census is conducted (i.e., years ending in 2 or 7). The ASM provides statistics on employment, payroll, supplemental labor costs, cost of materials consumed, operating expenses, value of shipments, value added, fuels and energy used, and inventories. The Economic Census, used for years ending in 2 or 7, is a survey of all employer establishments in the US that has been taken as an integrated program at 5-year intervals since 1967. Both the ASM and the Economic Census use NAICS classifications. The inventory data from the Economic Census and Annual Survey of Manufactures is broken into materials inventory, work-in-process inventory, and finished goods inventory. It is important to note that a finished product for an establishment in one industry might be reported as a raw material by an establishment in a different industry. For example, the finished product inventories of a steel mill might be included in the material inventories of a stamping plant. The inventory data does not have a breakout for transport time or down time; therefore, other data must be used for these purposes.

*Data on Plant Hours:* In order to estimate the work-in-process downtime (i.e., the time that materials are in work-in-process, but the plant is closed) one can employ data from the Survey of Plant Capacity Utilization. This data provides quarterly statistics on the rates of capacity utilization for the US manufacturing industry by NAICS code. In addition to providing capacity utilization, it also provides data on the average plant hours per week in operation for an industry.<sup>31</sup>

*Environmental Data:* For environmental data, this paper applies a suite of environmentally extended Input-Output databases for Life Cycle Assessments (LCA) developed under contract for NIST by Dr. Sangwon Suh of the Bren School of Environmental Science and Management at the University of California, Santa Barbara.<sup>32</sup> This data has been utilized in a number of environmental efforts, including NIST’s Building for Environmental and Economic Sustainability (BEES)<sup>33</sup> and Building Industry Reporting and Design for Sustainability (BIRDS)<sup>34</sup> software and related publications. This data utilizes the 12 TRACI 2 impact categories: global warming potential, primary energy consumption, human health – criteria air pollutants, human health – carcinogens, water consumption, ecological toxicity<sup>35</sup>, eutrophication<sup>36</sup>, land use, human health – non-carcinogens, smog formation, acidification, and ozone depletion. The units of measurement are provided in Table 1. This environmental data is organized by 2002 BEA codes for the Benchmark Input-Output tables, and matched and adjusted to the 2007 BEA Input-Output tables. The environmental data was adjusted from being in impact units per 2002 dollars to impact units per 2007 dollars using the consumer price index from the Bureau of Labor Statistics.

<sup>35</sup> The potential of a chemical released into the environment to harm terrestrial and aquatic ecosystems.

<sup>36</sup> The addition of mineral nutrients to the soil or water, which in large quantities can result in generally undesirable shifts in the number of species in ecosystems and a reduction in ecological diversity

*Labor Data:* The Bureau of Labor Statistics maintains an Occupational Employment Statistics (OES) program, which produces employment and wage estimates using the Standard Occupational Classification System and NAICS. The OES categorizations includes over 800 occupations and over 450 industries; however, archived data covers fewer industries (Bureau of Labor Statistics). The data is gathered through surveys and covers full-time and part-time wage and salary workers in nonfarm industries. The self-employed, owners and partners in unincorporated firms, household workers, or unpaid family workers are not covered in the survey. The data is available for the nation as a whole as well as by state, metropolitan area, and nonmetropolitan area. The OES surveys approximately 200 000 establishments every six months on a three-year survey cycle that results in 1.2 million establishments being surveyed. The data is provided by NAICS codes and by the Standard Occupational Classification System. Two industry categories of labor data were not available to be broken out: construction and agriculture. However, the costs of this labor are included in the capital purchases and industry purchases categories.

*Energy Data:* The Energy Information Administration collects energy data through the Manufacturing Energy Consumption Survey (Energy Information Administration). It is conducted on a quadrennial basis and samples approximately 15 500 establishments drawn from a nationally representative sample frame that includes 97 % to 98 % of the manufacturing payroll. Energy data is categorized by the NAICS codes and end use. For this analysis it is used to break the input-output data into more specific categories. This survey also provides the square footage of manufacturing floor space by NAICS code. This value is used to estimate the construction value of the buildings that house manufactured goods.

*Depreciable Assets Data:* In years ending in 2 or 7 the Economic Census is conducted, which is a survey of all employer establishments in the US where the response is required by law. It has been taken as an integrated program at 5-year intervals since 1967. Both the ASM and the Economic Census use NAICS classification; however, prior to NAICS the Standard Industrial Classification system was used. The Economic Census sent out nearly 4 million forms to businesses representing all US locations and industries. Four items from this data is used in this paper: gross depreciable assets, retirements, capital expenditures on buildings, and capital expenditures on machinery.

*Building Data:* RS Means provides data on construction costs for a range of building types and components. The cost per square foot of factory construction was used to estimate the value of constructed buildings housing manufacturing activity (RS Means 2005).

#### **4. Results and Discussion**

This paper develops a methodology using input-output data and analysis combined with other industry data to examine whether resources are disproportionately consumed in the production of a particular finished commodity, in this case automobiles, and if so, what activities account for this higher consumption. This case study provides a proof of concept in examining national level production for advancing efficiency in other manufacturing industries. The approach considers five measures of resource consumption: the amount of value added from each industry, the total cost of labor by occupation, the environmental impact from each industry, the value of associated gross depreciable assets, and the time it takes for a material to move through an industry (note that this flow time measure is only applicable to industries that handle materials). Flow time and the gross value of depreciable assets relate to the use of capital such as machinery and buildings. These two measures are only available for supply chain entities that are within the manufacturing industry; therefore, industries such as transportation and mining were examined using value added, labor hours, and environmental impact. Since this paper focuses on the distribution of resource consumption, the results are presented in terms of the percent of the total consumption of a particular resource and also in terms of percentile where the largest categories of consumption are among the highest percentile.

As seen in Figure 2, the results show that the consumption of resources is consistent with Pareto's principle where 20 % of the cause represents greater than 80 % of the resource consumption. That is, a

subset of supply chain entities represents a disproportional amount of the resource consumption. The results show that 20 % of supply chain entities account for 89 %, 89 %, and 91 % of value added, labor hours, and environmental impacts from automobile manufacturing, respectively. Improving the efficiency in these areas of the supply chain would lead to disproportional reductions in the resources needed for production. The distribution of value added, labor hours by industry, labor hours by occupation, and environmental impacts are such that they have a Gini coefficient of 0.87, 0.86, 0.86, and 0.87, respectively. The Gini coefficient is a measure of statistical dispersion where 0 represents equal distribution (i.e., each cost category represents the same proportion of total cost) and 1 represents total unequal distribution.

The results by industry for value added, labor hours, and environmental impact are shown in Table 2, Table 3, and Table 4, respectively. Each are categorized by industry NAICS code, which are categories of establishments, as illustrated in Figure 1. Table 2 shows that the final assembly of the automobile (NAICS 336111) is approximately 17 % of the total cost measured in value added, which means that nearly 83 % of the costs occur throughout establishments in the supply chain. “Wholesale trade” is the next highest (7.7 %) with sales people from this industry being a significant contributor (not shown). The 3<sup>rd</sup>, 4<sup>th</sup>, and 5<sup>th</sup> ranked supply chain entities are automobile parts industries (engine parts (336310), transmission and power train parts (336350), and other automotive parts (336390)). The “management of companies and enterprises” (e.g., company headquarters) is ranked 6<sup>th</sup>, which emphasizes the cost of operating large automobile manufacturing companies. These top 6 industries account for 45.6 % of the value added.

Labor hours in Table 3, Figure 3, and Table 6 are categorized by industry NAICS code; thus, it is the total labor occurring at categories of establishments. Labor is also categorized by occupation, as seen in Table 5. In terms of labor hours by industry, the final assembly (NAICS336111) (18.0 %), “wholesale trade” (9.5 %), and the “management of companies and enterprises” (5.6 %) activities are the largest consumers of labor. Moreover, these categories of establishments account for a larger proportion of labor hours than other categories of establishments in the supply chain. In terms of labor hours by occupation, “team assemblers” (14.5 %), “laborers and freight, stock, and material movers” (2.7 %), and “machinists” (2.5 %) are the largest contributors while five additional occupations account for 2.0 % to 2.5 % each and 16 account for 1.0 % to 2.0 %. These are the sum of labor hours throughout the supply chain for each occupation. If we recall the supply chain illustration in Figure 1, our approach is similar to summing the total labor hours in each industry for a particular occupation required to produce the finished commodity. Using either approach to categorize labor hours, labor is more broadly distributed across the supply chain than the value added.

Environmental impacts are categorized by industry NAICS codes. In terms of environmental impacts (Table 4), “automobile manufacturing” (22.0 %), “iron and steel mills and ferroalloy manufacturing” (6.3 %), “electricity and natural gas” (4.9 %), and “glass and glass product manufacturing (4.8 %) are the four largest contributors. Moreover, these categories of establishments account for a larger proportion of environmental impacts than other categories in the supply chain for automobile manufacturing.

Many of the same industries account for large fractions of value added, labor, and environmental impacts. Figure 3 and Table 6 identify those items that are above the 80<sup>th</sup> percentile for labor hours, environmental impact, and value added (i.e., those items that appear in Table 2, Table 3, and Table 4). There are 6 items that appear above the 95<sup>th</sup> percentile for all categories and 16 total items above the 90<sup>th</sup> percentile. “Electricity and natural gas” for all purposes (NAICS 2121, 2211, 2212) along with “glass and glass product manufacturing” (NAICS 327200), “iron and steel mills and ferroalloy manufacturing” (NAICS 331110), “automobile manufacturing” (NAICS 336111), “wholesale trade” (NAICS 420000), and “truck transportation” (NAICS 484000) were above the 95<sup>th</sup> percentile for all three measures. These establishment categories (i.e., NAICS codes), consume a disproportional amount of resources compared to other establishments in the automobile supply chain.

In addition to “Iron and steel mills and ferroalloy manufacturing” (NAICS 331110) being above the 95<sup>th</sup> percentile, a number of other metal and steel categories appear above the 90<sup>th</sup> percentile in all three measures, including “steel product manufacturing from purchased steel” (NAICS 331200), “ferrous metal foundries” (NAICS 331510), and “nonferrous metal foundries” (NAICS 331520). The high ranking of these metal and steel oriented categories emphasizes that the efficient use of steel can have a high impact on multiple resource measures relating to multiple stakeholders. There may also be opportunities for efficiency improvement in the use of metal and steel, as it is estimated that more than a quarter of steel is scrapped in the production process.<sup>37</sup> A number of entities have made this deduction and are focusing their research efforts on these efficiency improvements. For example, the National Institute of Standards and Technology has an automotive lightweighting group that examines these issues. The US Geological Survey estimates that 15 % of steel is scrapped when steel is cut, drawn, extruded, or machined.<sup>38</sup>

“Truck transportation” (NAICS 484000) appeared above the 95<sup>th</sup> percentile and “rail transportation” (NAICS 482000) appeared above the 90<sup>th</sup> percentile for all three measures. Additionally, “laborers and freight, stock, and material movers, hand” (SOC 537062) was the second largest labor occupation category in Table 5 and “heavy and tractor-trailer truck drivers” (SOC 533032) was 7<sup>th</sup>. The appearance of these items emphasizes that efficiency improvements in transportation throughout the supply chain can have a high impact on multiple resource categories relating to multiple stakeholders. There might be opportunities for efficiency improvement in this area, as approximately 20 % of truck miles are driven with no product being transported.<sup>39</sup> Reducing these empty miles would decrease labor, capital expenditures, and traffic. Several methods are being considered across the global economy to reduce these excess miles. In Germany, a new auction platform aims to improve truck space utilization.<sup>40</sup> Other efforts to co-load or ride-share have also received some attention. Innovative solutions like these might reduce the resources consumed in the transport of goods.

As previously mentioned, “wholesale trade” (NAICS 420000) appears above the 95<sup>th</sup> percentile for all three categories. Wholesalers sell or arrange the purchase/sale of goods to other businesses from a warehouse or office. Customers are, generally, reached through in-person communication, which might explain why “sales representatives” (SOC 414012) and “sales representatives, wholesale/manufacturing, technical/scientific products” (SOC 414011) are ranked 5<sup>th</sup> and 45<sup>th</sup> in labor hours in Table 5.<sup>41</sup> Advancing the dissemination of information on intermediate products might reduce the sales burden needed for distributing intermediate parts and components to producers. In addition to sales activity, wholesalers function as a warehouse to store inventory. Additional warehousing costs are categorized as “warehousing and storage” (NAICS 493000), which is above the 80<sup>th</sup> percentile in cost (Table 2), and labor hours (Table 3). Warehouses are needed to buffer for unpredictable fluctuations in demand. Improved forecasting in demand might lessen the need for inventory/warehousing and in turn reduce wholesale trade costs.

Figure 4 and Table 7 show manufacturing industries above the 70<sup>th</sup> percentile for environmental impact, flow time, labor hours, value added, and depreciable assets for automobile manufacturing. Figure 4 and Table 7 select supply chain entities only from establishments categorized as manufacturing entities that

handle intermediate components. These are the establishments that would, typically, be considered by a manufacturer to be a supplier. Other establishments categorized as non-manufacturing (e.g., management of companies and enterprises) are, therefore, not included. The 70<sup>th</sup> percentile is used, as there are very few industries where all five measures are above the 80<sup>th</sup> percentile. “Iron and steel mills and ferroalloy manufacturing” (NAICS 331110) is the only manufacturing supply chain entity that is above the 90<sup>th</sup> percentile for all five factors shown in Table 7. Only two additional items are at or above the 80<sup>th</sup> percentile: “other electronic component manufacturing” (NAICS 33441A) and “copper rolling, drawing, extruding and alloying” (NAICS 331420). These are the high resource consumption entities among those that would, typically, be considered a supplier.

## 5. Summary

This paper examines whether the resources used in the production of a specific commodity are consistent with the Pareto principle, and advances the identification of those supply chain entities that account for a disproportionately high level of resource consumption by examining automobile manufacturing as a case study. A multi-factor approach is used where the time, cost, labor, environmental impact, and depreciable assets are examined to facilitate the identification of economy-wide opportunities for efficiency improvement in manufacturing. Those production activities that consume high levels of resources across the different measures provide a strong opportunity for efficiency improvements affecting multiple stakeholders. The results suggest that the cost distribution is consistent with the Pareto principle where 20 % of the industries in the supply chain represent greater than 80 % of the total resource consumption. The data show that 20 % of supply chain entities account for 89 %, 89 %, and 91 % of value added, labor hours, and environmental impacts from automobile manufacturing, respectively. Six industries were above the 95<sup>th</sup> percentile in value added, environmental impact, and labor hours for automobile manufacturing while an additional 10 are above the 90<sup>th</sup> percentile. “Electricity and natural gas” for all purposes (NAICS 2121, 2211, 2212) along with “glass and glass product manufacturing” (NAICS 327200), “iron and steel mills and ferroalloy manufacturing” (NAICS 331110), “automobile manufacturing” (NAICS 336111), “wholesale trade” (NAICS 420000), and “truck transportation” (NAICS 484000) were above the 95<sup>th</sup> percentile for all three measures. Transportation, steel, sales, and warehousing appear in multiple ways (i.e., labor categories, industry categories, and different resource types) and there might be opportunities for efficiency improvement in these areas. For instance, for 20 % of the miles driven for truck transportation the truck is empty and more than a quarter of steel ends up as scrap, resulting in even more transportation.

For those supply chain entities that handle intermediate parts and components (i.e., the entities that would, traditionally, be considered suppliers), the environmental impact, time, labor hours, and depreciable assets were examined. One item is above the 90<sup>th</sup> percentile in all five categories, “Iron and steel mills and ferroalloy manufacturing” (NAICS 331110). This category also appeared in Figure 3, which is consistent with steel having a disproportional impact on multiple resource types. An additional two items are above the 80<sup>th</sup> percentile: “other electronic component manufacturing” (NAICS 33441A) and “copper rolling, drawing, extruding and alloying” (NAICS 331420). The areas identified in this paper as being above the 80<sup>th</sup> percentile in the consumption of multiple resource types provide strong opportunities for efficiency improvements that impact multiple stakeholders. Reducing resource consumption in these select areas will have a disproportional impact on total resource consumption, including costs and natural resources consistent with Pareto’s Principle.

Note: Electricity/natural gas can appear twice. One as the total (NAICS 212/221) and the uses of energy (e.g., NAICS 221100-B)

Table 5: Labor Hours for Automobile Manufacturing by Occupation, Top 20 %

Code	NAICS Description	% of Total	Code	NAICS Description	% of Total
512092	Team Assemblers	14.54%	131023	Purchasing Agents, Except Wholesale, Retail, and Farm Products	0.52%
537062	Laborers and Freight, Stock, and Material Movers, Hand	2.73%	113031	Financial Managers	0.50%
514041	Machinists	2.49%	514033	Grinding/Lapping/Polishing/Buffering Tool Setters/Operators/Tenders, Metal/Plastic	0.49%
511011	First-Line Supervisors of Production and Operating Workers	2.43%	491011	First-Line Supervisors of Mechanics, Installers, and Repairers	0.49%
414012	Sales Representatives (Wholesale and Manufacturing)	2.32%	414011	Sales Representatives, Wholesale/Manufacturing, Technical/Scientific Products	0.48%
512099	Assemblers and Fabricators, All Other	2.06%	131161	Market Research Analysts and Marketing Specialists	0.45%
533032	Heavy and Tractor-Trailer Truck Drivers	2.04%	339032	Security Guards	0.45%
519061	Inspectors, Testers, Sorters, Samplers, and Weighers	2.03%	131111	Management Analysts	0.45%
111021	General and Operations Managers	1.78%	412031	Retail Salespersons	0.44%
434051	Customer Service Representatives	1.65%	112022	Sales Managers	0.44%
439061	Office Clerks, General	1.46%	151121	Computer Systems Analysts	0.43%
499071	Maintenance and Repair Workers, General	1.39%	131071	Human Resources Specialists	0.43%
172112	Industrial Engineers	1.38%	151132	Software Developers, Applications	0.42%
499041	Industrial Machinery Mechanics	1.34%	436011	Executive Secretaries and Executive Administrative Assistants	0.41%
537051	Industrial Truck and Tractor Operators	1.26%	119041	Architectural and Engineering Managers	0.40%
514031	Cutting/Punching/Press Machine Setters/Operators/Tenders, Metal/Plastic	1.26%	519111	Packaging and Filling Machine Operators and Tenders	0.40%
435071	Shipping, Receiving, and Traffic Clerks	1.21%	514021	Extruding and Drawing Machine Setters, Operators, and Tenders, Metal and Plastic	0.39%
514121	Welders, Cutters, Solderers, and Brazers	1.14%	413099	Sales Representatives, Services, All Other	0.37%
132011	Accountants and Auditors	1.12%	519121	Coating, Painting, and Spraying Machine Setters, Operators, and Tenders	0.37%
514011	Computer-Controlled Machine Tool Operators, Metal and Plastic	1.11%	151151	Computer User Support Specialists	0.35%
433031	Bookkeeping, Accounting, and Auditing Clerks	1.07%	499043	Maintenance Workers, Machinery	0.35%
519198	Helpers--Production Workers	1.07%	373011	Landscaping and Groundskeeping Workers	0.34%
514111	Tool and Die Makers	1.04%	353021	Combined Food Preparation and Serving Workers, Including Fast Food	0.33%
519199	Production Workers, All Other	1.00%	516031	Sewing Machine Operators	0.32%
436014	Secretaries/Administrative Assistants, Except Legal/Medical/Executive	0.96%	493031	Bus and Truck Mechanics and Diesel Engine Specialists	0.30%
172141	Mechanical Engineers	0.91%	353031	Waiters and Waitresses	0.30%
113051	Industrial Production Managers	0.85%	173026	Industrial Engineering Technicians	0.29%
435081	Stock Clerks and Order Fillers	0.84%	519041	Extruding, Forming, Pressing, and Compacting Machine Setters, Operators, and Tenders	0.29%
514072	Molding/Coremaking/Casting Setters/Operators/Tenders, Metal/Plastic	0.83%	151133	Software Developers, Systems Software	0.29%
372011	Janitors and Cleaners, Except Maids and Housekeeping Cleaners	0.82%	514034	Lathe and Turning Machine Tool Setters, Operators, and Tenders, Metal and Plastic	0.29%
514081	Multiple Machine Tool Setters, Operators, and Tenders, Metal and Plastic	0.77%	151142	Network and Computer Systems Administrators	0.28%
472111	Electricians	0.77%	533031	Driver/Sales Workers	0.28%
537064	Packers and Packagers, Hand	0.75%	519122	Painters, Transportation Equipment	0.27%
431011	First-Line Supervisors of Office and Administrative Support Workers	0.71%	113021	Computer and Information Systems Managers	0.27%
533033	Light Truck or Delivery Services Drivers	0.70%	131081	Logisticians	0.27%
512022	Electrical and Electronic Equipment Assemblers	0.66%	499044	Millwrights	0.27%
514122	Welding, Soldering, and Brazing Machine Setters, Operators, and Tenders	0.61%	411012	First-Line Supervisors of Non-Retail Sales Workers	0.27%
131199	Business Operations Specialists, All Other	0.58%	434171	Receptionists and Information Clerks	0.27%
512031	Engine and Other Machine Assemblers	0.57%	231011	Lawyers	0.26%
435061	Production, Planning, and Expediting Clerks	0.53%	433021	Billing and Posting Clerks	0.25%
